Serum Human Epididymus Protein-4 (HE4) as a Biomarker in Ovarian Cancer and its Comparison with CA-125 in Benign and Malignant Cases

Swarnima Singh¹, Narayan Singh Jyala², Uday Kumar³, Rekha Kumari⁴

Abstract

Introduction: Ovarian cancer is the third leading site of cancer among women in India. 70% of ovarian cancers are diagnosed with advanced disease leading to high fatality rate. Human epididymis protein 4 (HE4), also known as WAP four disulphide core 2 (WFDC2), is a novel protein and is one of the more promising biomarkers for improving diagnostic performance in ovarian cancer detection.

Aim: To evaluate a new tumor marker, HE4, in comparison with CA-125 in diagnosis of ovarian cancer and benign gynecological diseases.

Material and Methods: Pre-operative serum HE4 and CA-125 were determined in 146 patients with benign gynecologic diseases and 100 patients with malignant gynecologic cancers (64 were epithelial ovarian cancers patients). HE4 and CA-125 cutoffs were 140 pmol/L and 35 kU/L, respectively. Sandwich Elisa, biotin-labelled antibody kit was used for HE4.

Results: HE4 demonstrated better specificity than CA 125 in benign gynecologic disease patients, with abnormal concentrations in 1.3% and 33.6%, respectively. A significantly higher area under the ROC curve was obtained with HE4 than with CA 125 in the differential diagnosis of gynecologic diseases (0.875 vs 0.723; p=0.0001). Both markers were clearly related to stage (HE4:p=0.004; CA-125: p=0.001).) and histopathological type (HE4: p =0.003 and CA-125: p=0.009 in serous papillary ovarian cancer).

Conclusion: HE4 has significantly higher diagnostic specificity than CA 125, and the combination of CA-125 and HE4 improved the detection of ovarian cancer in all stages and histological types. HE4 use may be important in the differential diagnosis of ovarian cancer.

Keywords: Biomaker, Carbohydrate antigen125, HE4, Human epididymis protein 4, Ovarian cancer.

Indian Journal of Medical Biochemistry (2019): 10.5005/jp-journals-10054-0095

Ovarian cancer is the most lethal gynecological cancer. In India, ovarian cancer is the third leading site of cancer among women, trailing behind cervix and breast cancer. The age-adjusted incidence rates of ovarian cancer vary between 1.7 and 15.2 per 100,000 population in different parts of the country. An increasing trend of this cancer has been observed since 1982 to date.¹

Ovarian cancer is primarily diagnosed in the post-menopausal women of the age group 55–64 years; 90% of the tumors are epithelial in origin.²⁻⁵ Germ cell tumor, usually diagnosed in the 20s, and sex cord stromal tumors which can be diagnosed at any age, form the remaining 10% of the ovarian tumors.⁶ Early course of the disease is asymptomatic and late stage disease symptoms are non-specific. Consequently, >75% of the tumors are diagnosed at an advanced stage. Mortality parallels disease stage: stages I and II have >70% of 5 year survival rate which drastically falls to <20% in stages III and IV.⁷ Early detection when tumors are small and still confined to the ovaries represents the best hope for mortality reduction and long term disease control.

CA-125 is the most commonly utilized tumor marker in ovarian carcinoma. CA-125 levels in conjunction with the imaging data and patient's medical and clinical findings are used to differentiate a benign from a malignant adnexal mass. Ultrasound and computed tomography scans though important, but equipments, experience and proper training may not be available at all centers in a developing country. Measuring serum CA-125 levels are more feasible but CA-125 concentrations are also increased in several benign gynecologic conditions like ovarian cysts, myomas and endometriosis.^{7-10,11} Likewise, benign effusions, renal or liver failure

and even pregnancy and menstrual cycles have an influence on the CA-125 concentrations.¹¹⁻¹³ This highlights the need of a simple, inexpensive biomarker that can be used alone or in combination with CA-125 to improve its sensitivity and specificity.

Some markers, including mesothelin, CA-72-4, inhibin, kallikreins, and osteopontin, have been investigated to complement CA-125 and to improve its sensitivity for early detection. Among these human epididymis protein 4 (HE4), is one of the most promising markers with better sensitivity and specificity than CA-125 for gynecological malignancies. It is a protein initially identified in the epithelium of the distal epididymis and may be involved in sperm maturation; it is also called WFDC2 because of its molecular structure, containing 2 whey acid protein domains and

a 4-disulfide-bond core with 8 cysteine residues. HE4 is expressed in the normal epithelium lining the male and female genital tracts (but not in normal ovarian epithelium), upper respiratory tract, and ducts of the salivary glands and breast, kidneys, gastrointestinal tract and endometrium. HE4 is strongly upregulated and overexpressed in ovarian carcinomas.¹⁴ Pathological conditions like lung adenocarcinomas, cystic fibrosis lungs, endometrial cancer, breast cancer, transitional cell carcinomas may also show overexpression.¹⁴⁻¹⁶

This study was undertaken (1) to evaluate serum HE4 concentrations in benign and malignant gynecologic diseases (2) to explore the clinical usefulness of HE4 (3) to compare the diagnostic performance of HE4 with that of CA-125.

MATERIAL AND METHODS

246 patients (146 benign gynecological cases, 100 malignant gynecological cases) were enrolled after approval from the Ethics Committee. The inclusion criteria were: patients diagnosed with a pelvic mass of suspected ovarian origin, availability of complete clinical records, informed consent and agreement to have additional testing for new markers, clinical and histological diagnosis with staging and grading of ovarian cancer, where required.

Exclusion criteria were: pregnancy, and significant concomitant diseases such as chronic heart failure, and severe chronic liver or renal disease.

Blood samples were collected in serum separator tube (SST) and allowed to clot for 30 minutes at room temperature before centrifugation for 15 minutes at 1000 x g. Serum was removed, aliquoted and stored at \leq -20 °C, for analysis within 3 months.

CA-125 was measured on Beckman coulter Access 2 immunoassay based on chemiluminiscence.. Cut off was 35 kU/L. Serum HE4 concentrations were measured using solid phase quantitative sandwich enzyme immunoassay technique (RnD Systems). Assay was run according to manufacturer's protocol. Cut off for HE4 was 140 pmol/L. Serum creatinine concentrations were measured in all the participants (patients and controls) by use of Jaffe's alkaline picrate method on AU400 (Olympus Diagnostics); values below 1.3 mg/dL (115 μ mol/L) were defined to be within the reference range. All the other relevant clinical information were taken from patient's file.

STATISTICAL ANALYSIS

Data was analyzed on Excel and SPSS 21.0 software. Median values were calculated for skewed data. Mann-Whitney U test and Kruskall-Wallis test were used to compare the statistical significance

between categories. The level of significance was set at p<0.05. ROC curves were drawn to assess and compare the roles of HE4 and CA-125.

Results

Patient Characteristics

The serum of 246 patients were analyzed: 146 (59.3 %) had benign disease and 100 (40.7 %) had malignant disease. Benign gynecologic group was younger and evidently premenopausal. Malignant gynecologic group was comparatively older, more likely to be post menopausal and having a family history of ovarian or breast cancer (Table 1).

Tumor Characteristics

The most common benign ovarian tumours were ovarian cysts (cystadenomas (n = 48), cystadenofibromas (n = 24), endometriomas (n = 33), fibroids (n = 29) and endometrial polyps(n = 06). Other benign tumors (06) encountered were mature teratoma (02), hydrosalpinx (01), functional cyst (01), struma ovarii (01), leydig cell tumor (01). Amongst 100 gynecological cancers: epithelial ovarian cancers (EOC) (64), endometrial cancers (17), endocervical cancers (10), squamous cell carcinoma (09). Most of the EOC were of high grade and were diagnosed at an advanced stage (Table 2).

Tumor Marker Levels

Interestingly, HE4 showed a higher diagnostic specificity than CA15 in benign gynecologic disease patients. Only 1.3% of the benign gynecologic disease patients had HE4 concentrations above the reference interval, compared to 33.6% for CA-125 (Tables 3 and 4).

In malignant samples the median (SE) concentration of HE4 was 116.8 (25.4) pmol/L and of CA 125 was 44.2 (47.9) kU/L. The most common malignancy for which patients exhibited increased concentrations of HE4 and CA 125 was epithelial ovarian cancer (75.2% and 80% of samples, respectively). Significantly higher HE4 (p = 0.001) and CA 125 (p = 0.01) serum concentrations were found in patients with ovarian cancer than in patients with other gynecologic cancers (p = 0.001) (Table 5).

Table 6 shows the serum HE4 and CA-125 concentrations in different stages and histological types of ovarian cancer patients, excluding 1 patient with renal failure. Both HE4 and CA-125 were well-related to the tumor stage with significantly higher concentrations in stages III and IV (HE4: p = 0.004; CA-125: p = 0.001) than in stages I and II. Both the markers, however, did not show

significant differences between stage III and IV. For stages I-II, HE4 and CA-125 individually demonstrated a sensitivity of 58.3% and 50% respectively, which on combination increased to 75%. Likewise, for stages III and IV, sensitivity on combination approached to 96%. Serum concentrations of HE4 (p = 0.009) and CA-125 (p = 0.003) were significantly higher in serous papillary ovarian tumor than other histological types. Diagnostic sensitivity on combination, improved across all histological types and both markers were well-related to the histological type of ovarian cancer.

ROC Curves

ROC curves were plotted to compare the diagnostic performances of HE4 and CA-125 in (A) gynecologic cancers vs benign gynecologic diseases and (B) ovarian cancer vs other gynecologic diseases. A significantly higher area under the curve was observed with HE4 in comparison to CA-125 (0.875 vs 0.723, p = 0.0001 and 0.903 vs 0.797, p = 0.0003).

DISCUSSION

In clinical practice, serial serum CA-125 measurements and ultrasonography are used as an aid to diagnose early ovarian cancer in asymptomatic post menopausal women.^{7,10,17} One major fallacy with using CA-125 as a screening tool is that about 20% of the ovarian tumors do not express the antigen.^{7-10,17} It therefore seems prudent to combine CA-125 with new tumor marker(s) to increase its diagnostic efficacy.^{7,9,10,17,18}

An important concern for CA 125 is its low diagnostic specificity. Several benign and malignant diseases, other than ovarian cancers may show abnormal CA-125 concentrations.^{7-11,19,20} This lack of specificity may be confounding in some benign gynecologic diseases such as endometriosis, commonly diagnosed in premenopausal women. Despite these controversies, CA 125 is still being used in the differential diagnosis of pelvic masses, assessment of response to treatment, and as a prognostic factor for early diagnosis of recurrence.^{7,8,10}

HE4 protein is encoded by WAP four-disulfide core domain 2 (*WFDC2*) gene which is frequently over-expressed in ovarian carcinomas.¹⁴ In ovarian cancers, but not in normal tissue, this HE4 protein gets N-glycosylated with an apparent molecular weight of 25 kDa. Then it is secreted into the extracellular environment to become detectable in the blood or urine of patients via

enzyme immunoassay[16, 20]. It is highly stable on a wide range of pH and temperature. Other tissues like lung, endometrial, and breast adenocarcinomas, mesotheliomas, and rarely, kidney gastrointestinal, and transitional cell cancers have also reported some expression.^{18,19} Previous studies indicate that normal ranges for HE4 are 51.3- 78.4 pmol/l (females) and 43.4–69.7 pmol/L (males).^{21,22}

We found that HE4 serum concentrations were less likely to be increased in benign gynecologic conditions than CA-125. Here HE4 was increased in only 1.3% (2/146) of patients with benign gynecologic disease where as CA 125 showed an increase in 33.6% (49/146) of patients with benign gynecologic conditions. None of our 33 patients with endometriosis had high HE4 serum levels whereas 42.4% patients had high CA 125 concentrations. These results establish the correctness of previously published findings and distinctly prove the usefulness of HE4 in the differential diagnosis of ovarian carcinoma from other gynecologic conditions.^{9,11-15,21-25}

Similar to other tumor markers, renal failure is the most important source of false positivity during the exposition of HE4 results. So, in patients with renal failure or those with abnormal serum creatinine concentrations, HE4 results should be interpreted cautiously.^{26,27} This is vital, because acute renal failure may be found in some patients undergoing chemotherapy. Therefore we excluded 1 ovarian cancer patient with renal failure from our study.

HE4 has been advocated as a promising biomarker for ovarian cancer. HE4 showed higher median concentrations and diagnostic sensitivity in ovarian carcinoma than the clinically more popular CA-125. Our data corroborate with previous studies of HE4 in ovarian or gynecologic tumors. Minor differences observed may be due to population characteristics.⁹

Both HE4 and CA-125 were well-related to the tumor stage and histological type. Diagnostic sensitivity of HE4 was similar or higher than CA-125 in early stages, and CA-125 showed marginally higher sensitivity in advanced stages. Significantly higher differences in the median concentrations were observed for both HE4 and CA-125 in early stages than in advanced disease. This may be due to the lower concentrations of the biomarkers in the early stages. The point to consider is that both the biomarkers are complementary showing much higher diagnostic sensitivity in combination. Nonetheless, the specificity of the combination dropped due to the high CA-125 false positivity in other gynecologic conditions, especially in premenopausal women.

ROC curve shows the higher HE4 diagnostic specificity and similar diagnostic sensitivity compared with CA-125, accounting for the more pragmatic approach of HE4 in the differential diagnosis of gynecologic diseases.^{9,15}

Limitations

These are hospital referred patients, so do not necessarily represent the true distribution of cancer subtypes. Reference levels for the Indian population could be calculated and used for better diagnostic performances of serum HE4.

One well recognized source of false-positivity with CA-125 is the presence of effusions. Studies have shown that effusions had less influence on HE4 results than on CA 125²⁹ but we have not evaluated patients with benign or malignant effusions separately.

Abnormal serum concentrations have also been reported in other non-gynecologic cancers like Non small cell lung carcinoma (NSCLC), liver cancers.^{27,30} So we humbly understand that there is scope of further studies on these aspects.

CONCLUSION

HE4 showed higher diagnostic specificity than CA-125 in benign gynecologic diseases. It demonstrated its usefulness in the differential diagnosis of ovarian from non-ovarian gynecologic cancers. It was well related to the stage and histological type and the combination of HE4 with CA-125 enhanced the diagnostic sensitivity for ovarian tumors.

Funding: None

Conflicting Interest: This is to certify that the study "Serum Human Epididymus protein-4 (HE4) as a biomarker in ovarian cancer and its comparison with CA-125 in benign and malignant cases " has no potential , perceived, or real competing and/or conflicts of interest with the other departments and members involved in the same study.

Ethical approval: The study was duly approved by the Institutional research committee. All the ethical guidelines and standards were followed. Prior written informed consent was obtained from all the participants.
